(moclobemide)

Tablets

ACTIONS AND CLINICAL PHARMACOLOGY

MANERIX (moclobemide) is a short-acting, Reversible Inhibitor of Monoamine oxidase type A (RIMA). It is a benzamide derivative which inhibits the deamination of serotonin, noradrenaline and dopamine. This action leads to increased concentrations of these neurotransmitters, which may account for the antidepressant activity of moclobemide.

Monoamine oxidases are currently subclassified into two types, A and B, which differ in their substrate specificity. Moclobemide preferentially inhibits MAO-A; at a 300 mg dose, the inhibition of MAO-A is approximately 80%, while that of MAO-B is approximately 20 - 30%. The estimated MAO-A inhibition is short-lasting (maximum 24 hours) and reversible.

PHARMACOKINETICS

Volunteers

General: Following oral administration, MANERIX (moclobemide) is 98% absorbed from the gastrointestinal tract. Due to hepatic first pass effect, absolute bioavailability is approximately 55% after single doses, but 90% after multiple doses. The apparent volume of distribution is approximately 1.2 L/kg, indicating extensive tissue distribution.

MANERIX is extensively metabolized, largely via oxidative reactions on the morpholine moiety of the molecule. While 95% of the administered dose is excreted in the urine, less than 1% of this is in the unchanged form. Active metabolites recovered *in vitro* or in animal experiments are present only at very low concentrations in the systemic circulation in man. MANERIX is 50% bound to plasma proteins, mainly to albumin. The presence of food reduces the rate, but not the extent of MANERIX absorption.

Single Dose: Following the administration of a 100 mg single oral dose of MANERIX to healthy subjects, peak plasma concentrations ranged from 488 ng/mL to 1,450 ng/mL (mean C_{max} : 849 ng/mL) and were reached in 0.5 to 3.5 hours (mean T_{max} : 49 min). The elimination half-life is 1.5 hours. Up to 200 mg, the pharmacokinetics of MANERIX are linear. At higher doses, non-linear pharmacokinetics are observed. In a dose range of 400 mg to 1,200 mg, maximum plasma concentrations increased and clearance decreased in a non dose-proportional manner. With increasing doses, the elimination half-life also becomes prolonged.

Multiple Dose: During the second week of a 100 mg t.i.d. dosing regimen in healthy subjects, the steady-state trough concentrations of MANERIX ranged between 114 ng/mL and 517 ng/mL. An increase in the dose to 150 mg t.i.d. resulted in a greater than proportional increase in MANERIX steady-state trough concentrations, namely to concentrations ranging between 346 ng/mL and 1,828 ng/mL

Patients

Hepatic Impairment, Single Dose: In patients with liver cirrhosis, the administration of a single 100 mg dose of MANERIX resulted in approximately a three-fold increase in peak plasma concentrations (C_{max} : 1,607 ng/mL), and elimination half-life ($t_{1/2\beta}$: 4.0 hr), while clearance decreased about four-fold (Cl 337 mL/min).

Renal Impairment, Single Dose: In patients with renal insufficiency, the administration of a single 100 mg dose of MANERIX did not appreciably alter the pharmacokinetics of the drug, except for an increase in absorption time.

Elderly Patients, Single and Multiple Dose: Following a 100 mg t.i.d. dosing regimen in elderly subjects (65 to 77 years old), C_{max} and AUC values were somewhat higher than in young subjects (21 to 34 years old), namely 1,498 versus 950 ng/mL and 5,571 versus 3,102 ng•h/mL, respectively. Clearance in the elderly was reduced (19.7 versus 32.3 L/h).

Slow Metabolisers: Because MANERIX is partly metabolized by polymorphic isozymes (CYP2C19 and CYP2D6), blood levels of the drug can be affected in patients with genetically or drug-induced poor metabolism. Approximately 2% of the caucasian population and 15% of the asian population can be genetically phenotyped as slow metabolisers with respect to oxidative hepatic metabolism. It was found that the area under the curve (AUC) measurement in slow metaboliser subjects was approximately 1.5 times greater than in extensive metaboliser subjects for the same dose of MANERIX. This increase is within the normal range of variation (up to two-fold) typically seen in patients.

INDICATIONS AND CLINICAL USE**Adults**

MANERIX (moclobemide) is indicated for the symptomatic relief of depressive illness.

Pediatrics < 18 years of age: the safety and efficacy of MANERIX has not been established in the pediatric population, therefore its use is not recommended.

CONTRAINDICATIONS

MANERIX (moclobemide) is contraindicated in the following circumstances:

- In patients with a known hypersensitivity to MANERIX or any component of the product. As with any other exogenous compound the possibility of hypersensitivity reaction should be considered in susceptible patients. Symptoms of hypersensitivity may include rash and edema.
- In patients in an acute confusional state.
- Concomitantly with tricyclic antidepressants (see DRUG INTERACTIONS, Other Antidepressants).

- In combination with selective serotonin reuptake inhibitors (SSRIs) or conventional monoamine oxidase (MAO) inhibitors (see DRUG INTERACTIONS, Other Antidepressants).
- In combination with selegiline (see DRUG INTERACTIONS)
- In combination with meperidine. Although there is limited experience with the concomitant use of MANERIX and narcotics, death has occurred in patients receiving a conventional MAO inhibitor and meperidine (pethidine) given concomitantly.
- Concomitantly with thioridazine (see PRECAUTIONS and DRUG INTERACTIONS).

WARNINGS

Potential Association with the Occurrence of Behavioural and Emotional Changes, Including Self-Harm

It is unknown whether increased risk of suicidal ideation and behaviour is associated with the use of older antidepressants (eg MANERIX) in pediatric patients and/ or adults. However, recent analyses of placebo-controlled clinical trial safety databases from SSRIs and other newer antidepressants suggest that use of these drugs may be associated with behavioural and emotional changes, including an increased risk of suicidal ideation and behaviour over that of placebo. Thus, rigorous clinical monitoring for suicidal ideation or other indicators of potential for suicidal behaviour is advised in patients of all ages given any antidepressant drug. This includes monitoring for emotional and behavioural changes.

PRECAUTIONS

General

In patients with thyrotoxicosis or pheochromocytoma, conventional MAO-inhibitors may precipitate a hypertensive reaction. Because there are no data available on the use of MANERIX in such patients, caution is advised when prescribing MANERIX to these subjects.

Occupational Hazards

Patients should be cautioned against driving an automobile or performing hazardous tasks until they are certain of the effect that MANERIX has on them.

Use in Pregnancy

Safety of use in pregnancy has not been established. Therefore, MANERIX is not recommended in women who may be pregnant, unless, in the opinion of the physician, the expected benefits to the patient markedly outweigh the possible risk to the fetus.

Nursing Mothers

Clinical data suggest that small quantities of MANERIX are excreted in human milk. Therefore, MANERIX is not recommended in nursing mothers unless the anticipated benefits outweigh the potential harm to the infant.

Hepatic Dysfunction

In patients with severe liver dysfunction, the daily dose of MANERIX should be substantially reduced to one-third or one-half of the standard dose (see ACTIONS AND CLINICAL PHARMACOLOGY - PHARMACOKINETICS).

Renal Dysfunction

Single dose pharmacokinetic data suggest that no dosage adjustment may be required in patients with impaired renal function (see ACTIONS AND CLINICAL PHARMACOLOGY - PHARMACOKINETICS). However, multiple dose studies with MANERIX have not been performed in patients with renal dysfunction, therefore, MANERIX should be used with caution in this patient population. In normal volunteers, the absolute bioavailability almost doubles following multiple dosing as compared to a single dose.

Dextromethorphan

Co-administration of MANERIX and dextromethorphan which may be contained in cough and cold medicines is not recommended (see DRUG INTERACTIONS).

Thioridazine

A study to evaluate the potential of MANERIX to inhibit the cytochrome enzyme P4502D6 (P4502D6) concluded that MANERIX can affect the pharmacokinetics of drugs (such as thioridazine) that are mainly metabolized by P4502D6. Thioridazine administration results in a dose-dependent prolongation of the QTc interval, which may cause serious ventricular arrhythmias including torsades de pointes-type arrhythmias and sudden death. This risk is expected to increase with MANERIX-induced inhibition of thioridazine metabolism (see CONTRAINDICATIONS and DRUG INTERACTIONS).

DRUG INTERACTIONS

Selegiline

Studies revealed that the combination of moclobemide and selegiline had a supra-additive effect to the tyramine sensitivity. The tyramine sensitive factor was increased with an individual variability. It was expected that the effect of oral tyramine might potentiate this effect to an even greater extent. It was therefore concluded that food containing tyramine should be omitted. Under daily conditions an absolute omission of food with tyramine is almost impossible. Based on the individual variability of the increase in sensitivity it is also not possible to recommend a specific amount which would be still well tolerated. Therefore the combination of moclobemide and selegiline is contraindicated.

Cimetidine

Cimetidine doubles the AUC (area under the plasma concentration-time curve) of MANERIX (moclobemide) and is expected to approximately double MANERIX steady-state concentrations.

In patients receiving MANERIX concomitantly with cimetidine, a 50% reduction in the dosage of MANERIX may be necessary.

Tyramine

During studies conducted at the maximum recommended MANERIX dose of 600 mg/day, the mean dose of tyramine required to produce a 30 mm Hg increase in systolic blood pressure was 148 ± 50 mg (76 - 200 mg) when MANERIX was administered immediately after tyramine. The threshold dose of tyramine was reduced to 84 ± 23 mg (54 - 112 mg) when the sequence of administration was reversed so that MANERIX was administered one hour before tyramine. These findings indicate that the potentiation of tyramine may be minimized by administering MANERIX after, instead of prior to, a tyramine-enriched meal. There is limited experience in patients who took MANERIX before meals. Most clinical trial protocols specified that the drug be taken immediately after meals. Therefore, patients should be instructed to take MANERIX immediately after meals .

Treatment with MANERIX does not necessitate special dietary restrictions. In clinical studies it was demonstrated that up to 100 mg tyramine can be safely ingested during treatment with MANERIX 600 mg/day when MANERIX was given after meals. This amount of tyramine, 100 mg, corresponds to 1,000 g to 2,000 g mild or 200 g strong cheese, or to 70 g Marmite yeast extract.

As a safety measure, patients should be urged to report immediately the abrupt occurrence of any of the following symptoms; occipital headache, palpitations, neck stiffness, tachycardia or bradycardia or other atypical or unusual symptoms not previously experienced.

Other Antidepressants

Concomitant Use: Clinical interaction studies between MANERIX and a tricyclic antidepressant (clomipramine) resulted in severe adverse reactions (see CONTRAINDICATIONS). Data involving other tricyclic antidepressants are limited. Therefore, the concomitant use of MANERIX and tricyclic antidepressants is contraindicated.

Clinical data are not available on the concomitant use of MANERIX and selective serotonin reuptake inhibitors, or conventional monoamine oxidase inhibitors. Therefore, until clinical data become available, MANERIX should not be administered in combination with these agents.

Sequential Use: Treatment with a tricyclic antidepressant may be initiated following the discontinuation of MANERIX with a short washout period of no less than two days.

When switching patients from serotonergic antidepressants to a conventional MAO-inhibitor, it is standard practice to allow for a washout period equivalent to at least 4-5 half-lives of the previously administered drug or any active metabolites. This recommendation also applies to MANERIX.

Prozac

An exception is Prozac (fluoxetine); at least five weeks should elapse between its discontinuation and initiation of treatment with MANERIX.

Buspirone

To date, there is no experience regarding the co-administration of MANERIX and buspirone. Therefore, patients should be carefully monitored should concomitant administration be implemented.

Antipsychotics

In depressed patients with schizophrenic or schizoaffective disorder, psychotic symptoms may be exacerbated during treatment with MANERIX. There is little experience regarding the concomitant

use of MANERIX and antipsychotic drugs. Therefore, patients should be carefully monitored should concomitant treatment be undertaken.

Thioridazine

A study to evaluate the potential of moclobemide to inhibit the cytochrome enzyme P4502D6 (P4502D6) concluded that moclobemide can affect the pharmacokinetics of drugs (such as thioradazine) that are mainly metabolized by P4502D6. Thioridazine administration results in a dose-dependent prolongation of the QTc interval, which may cause serious ventricular arrhythmias including torsades de pointes-type arrhythmias and sudden death. This risk is expected to increase with moclobemide-induced inhibition of thioridazine metabolism (see CONTRAINDICATIONS).

Alcohol

Excessive alcohol consumption should be avoided. Alcohol interaction studies were performed at blood alcohol concentrations of 0.05%. However, no studies were conducted at blood alcohol concentrations recognized as legally intoxicating.

Anesthetic Agents

While specific data on the use of MANERIX in patients undergoing anesthesia are not available, based on its reversible action and short elimination half-life (see ACTIONS AND CLINICAL PHARMACOLOGY) 'Manerix' should be discontinued no less than two days before the administration of anesthetic agents, especially spinal or local anesthetic agents that contain epinephrine.

In animals, moclobemide has been shown to potentiate the effects of opiates. The combination of moclobemide and meperidine (pethidine) is not recommended (see CONTRAINDICATIONS). Other opioid analgesics should be used with extreme caution, if at all, and a dosage adjustment may be necessary for these drugs.

Sympathomimetics

Following multiple oral doses of MANERIX (total dose: 600 mg/day), a phenylephrine -induced increase in systolic blood pressure was potentiated (1.6 times) after intravenous administration. Patients should be advised to avoid the concomitant use of sympathomimetic amines (e.g., amphetamine and ephedrine like compounds contained in many proprietary cold, hay fever or weight-reducing preparations), until further studies have been conducted.

Dextromethorphan

In isolated cases, the co-administration of MANERIX and dextromethorphan resulted in adverse events, including vertigo, tremor, nausea and vomiting. Since cough and cold medicines may contain dextromethorphan, they should not be taken without prior consultation with the physician, such that non-dextromethorphan containing alternatives may be given (see PRECAUTIONS).

Antihypertensive Agents

Clinical trials with MANERIX have shown inconsistent effects on the blood pressure of hypertensive patients. Therefore, careful monitoring is recommended during initial treatment.

ADVERSE REACTIONS

The following table lists the adverse events reported during clinical trials in which 1,922 patients were treated with 50-600 mg/day MANERIX (moclobemide) for depressive illness. Limited

experience in 60 patients treated with 601 to 750 mg/day of MANERIX suggests that the incidence of adverse reactions may increase at higher doses.

Clinical Adverse Events > 1%

Organ System	Adverse Event	%	
		Moclobemide (n = 1922)	Placebo (n = 271)
Central Nervous System	headache, pressure in head	8.0	11.1
	Insomnia, sleep disturbances	7.3	4.8
	dizziness	5.1	8.1
	tremour	5.0	3.0
	increased agitation	4.5	2.6
	restlessness, nervousness	4.1	2.6
	sleepiness, somnolence	3.7	5.5
	tiredness, sedation	3.0	4.1
	increased anxiety, acute anxiety state	2.8	2.2
	weakness or faintness	1.2	1.8
Gastrointestinal	nausea	5.2	4.8
	constipation	3.9	3.3
	gastrointestinal pain, epigastric discomfort	2.3	2.6
	sickness	1.9	1.1
	diarrhea	1.8	1.1
	abdominal fullness, abdominal pain	1.6	1.5
	vomiting	1.6	0.4
Cardiovascular	tachycardia, palpitations	3.8	3.3
	hypotension	3.0	0.4
	orthostatic, reactive hypotension	2.3	3.3
Anticholinergic	dry mouth	9.2	10.7
Miscellaneous	sweating	2.4	2.2
	blurred vision	1.8	1.1
	increase/loss of appetite	1.3	1.8

Other clinical adverse events with an incidence of < 1% in clinical studies, or reported in post-marketing surveillance, are as follows:

Psychiatric: Difficulties falling asleep, nightmares/dreams, hallucinations, memory disturbances, confusion, disorientation, delusions, increased depression, excitation/irritability, hypomanic symptoms, aggressive behaviour, apathy, tension.

Cases of suicidal ideation and suicidal behaviours have been reported during antidepressant therapy or early after treatment discontinuation (see WARNINGS)

Central and Peripheral Nervous System: Migraine, extrapyramidal effects, tinnitus, paresthesia, dysarthria.

Gastrointestinal: Heartburn, gastritis, meteorism, indigestion.

Cardiovascular: Hypertension, bradycardia, extrasystoles, angina/chest pain, phlebitic symptoms, flushing.

Dermatological/Mucocutaneous: Exanthema/rash, allergic skin reaction, itching, gingivitis, stomatitis, dry skin, conjunctivitis, pruritus, urticaria.

Genito-Urinary: Disturbances of micturition (dysuria, polyuria, tenesmus) metrorrhagia, prolonged menstruation.

Miscellaneous: General malaise, skeletal/muscular pain, altered taste sensations, hot flushes/cold sensation, photopsia, dyspnea, visual disturbances.

Laboratory Abnormalities

Laboratory examinations were performed in a total of 1,401 patients during clinical trials with MANERIX. Reductions were observed in leucocyte, SGOT and SGPT values, however, these reductions were attributed to raised baseline values returning to normal, and were not considered clinically relevant. No other laboratory abnormalities were noted during clinical trials.

In post-market surveillance, there appeared to be a low incidence of raised liver enzymes, without associated clinical sequelae.

SYMPTOMS AND TREATMENT OF OVERDOSAGE

Symptoms

Signs and symptoms of overdosage with MANERIX (moclobemide) include nausea, vomiting, drowsiness, disorientation, slurred speech, amnesia, reduced reflexes, agitation, hypertension and convulsions. One patient remained stuporous for 36 hours following an overdose with 1,550 mg MANERIX. All abnormal laboratory values and vital signs returned to within normal range one to five days after overdosage. No organ toxicity was reported.

Treatment

The treatment of overdosage should consist of general supportive measures. Gastric lavage or induction of emesis, activated charcoal and fluid control may be of benefit.

As with other antidepressants, mixed overdoses of MANERIX with other drugs (e.g. agents active on the CNS), could be life-threatening. Serotonergic syndrome and death have been reported after combined overdose of MANERIX and other antidepressants. Therefore, such patients should be closely monitored so that appropriate care and treatment may be given.

DOSAGE AND ADMINISTRATION

NOTE: MANERIX (moclobemide) should always be taken after meals (see DRUG INTERACTIONS).

Usual Adult Dosage

The administration of MANERIX should be initiated at 300 mg daily dose (in two divided doses), and increased gradually to a maximum of 600 mg/day if needed, noting carefully the clinical response and any evidence of intolerance. Individual patient response may allow for a reduction of the daily dose. As with other antidepressants, it should be kept in mind that there may be a lag time in therapeutic response. There is no evidence that increasing the dosage rapidly shortens this latent period and may, in fact, increase the incidence of side-effects. Furthermore, because bioavailability of MANERIX has been shown to increase over the first week of dosing (see PHARMACOKINETICS), the initial daily dose of 300 mg should not be increased until after this first week of therapy.

Liver Dysfunction

When hepatic metabolism is severely impaired by hepatic disease or inhibited by a drug that affects microsomal mixed function oxidase activity (e.g. cimetidine), the daily dose of MANERIX should be reduced to one-third or one-half of the standard dose.

Renal Dysfunction

Single dose pharmacokinetic data suggest that no dosage adjustment may be required in patients with impaired renal function. However, multiple dose studies with MANERIX have not been performed in patients with renal dysfunction, therefore, MANERIX should be used with caution in this patient population. In normal volunteers, the absolute bioavailability almost doubles following multiple dosing as compared to a single dose.

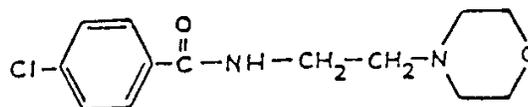

Elderly

No dosage adjustments are necessary in elderly patients.

Cimetidine

Cimetidine doubles the AUC (area under the plasma concentration-time curve) of MANERIX and is expected to approximately double MANERIX steady-state concentrations (see DRUG INTERACTIONS).

In patients receiving MANERIX concomitantly with cimetidine, a 50% reduction in the dosage of MANERIX may be necessary.

PHARMACEUTICAL INFORMATIONi) **Drug Substance:****Proper Name:** moclobemide**Chemical Name:** p-chloro-N-(2-morpholinoethyl)benzamide**Structural Formula:****Molecular Formula:** C₁₃H₁₇ClN₂O₂**Molecular Weight:** 268.74

Description: Moclobemide is an almost white crystalline powder with a faint odour. It is slightly soluble in water. pK_a is approximately 6.2. The partition coefficient in a pH 7.4 octanol/buffer solution at 22°C is approximately 40. The melting point is approximately 138°C.

ii) **Composition:**

Each film-coated tablet contains either 150 mg or 300 mg moclobemide. The non-medical ingredients are as follows:

150 mg tablets: cornstarch, ethylcellulose, iron oxide, lactose, magnesium stearate, methylhydroxypropyl cellulose, polyethylene glycol, povidone, sodium starch glycolate, talc, titanium dioxide.

300 mg tablets: cornstarch, ethylcellulose, lactose, magnesium stearate, methylhydroxypropyl cellulose, polyethylene glycol, povidone, sodium starch glycolate, talc, titanium dioxide.

iii) **Stability and Storage Recommendations:**

Store at 15-30°C.

Pr MANERIX®
(moclobemide)
150 mg and 300 mg tablets

Information for the Patient

You have been prescribed MANERIX® (pronounced Man-er-ix) by your doctor. Reading this information can help you learn about MANERIX (moclobemide) and how to make this medicine work best for you. This brochure does not provide all known information about MANERIX. If you have any questions or concerns about your treatment, please speak with your doctor or pharmacist.

What is MANERIX?

- 'Manerix' is a prescription medication used to treat symptoms of depression. It belongs to the family of drugs called RIMA (Reversible Inhibitor of Monoamine Oxidase-type A). These antidepressants act by changing levels of certain chemicals in the brain.

•

What should you tell your doctor before you start taking MANERIX?

Before beginning treatment with MANERIX, make sure your doctor knows if:

- you have ever had a bad reaction to moclobemide (MANERIX) or any of the inactive ingredients.
- you are allergic to other medicines, food and dyes.
- you are taking ANY other medicines (prescription or nonprescription) particularly cimetidine, meperidine, selegiline, thioridazine, buspirone, clomipramine, anesthetics, other antidepressants, blood pressure medications, cough and cold medications containing dextromethorphan, allergy medications, or medications used to treat certain mental illnesses other than depression.
- you have any other illnesses/diseases, including a history of liver or kidney disease, thyroid disorders, heart problems, or high blood pressure.
- you are pregnant, plan on becoming pregnant, or are breast-feeding a child.
- you have a habit of excessive alcohol consumption.

This information will help your doctor and you decide whether you should use MANERIX and what extra care may need to be taken while you are on the medication. You should always consult your doctor or pharmacist before using other medications while on MANERIX.

When not to take MANERIX

- Do not take MANERIX if you are allergic to it or to any of the components of its formulation (see list of components under **What does MANERIX contain?**). Stop taking the drug and call your doctor immediately if you experience an allergic reaction (skin rash, hives, etc.) or any unusual or severe side effects.
- Do not take MANERIX if you are currently taking selegiline, thioridazine or clomipramine.

How should MANERIX be taken?

Your doctor has prescribed MANERIX after carefully studying your case. Other people may not benefit from taking this medicine, even though their problems may seem similar to yours. Do not give your MANERIX to anyone else.

- Take this medicine only as directed by your doctor. Do not take more of it, do not take it more often, and do not take it for a longer time than your doctor ordered.
- Don't stop taking MANERIX as soon as you start feeling better. Discuss how long drug treatment should continue, especially if you have had more than one episode of depression.
- The starting dose of MANERIX should be 300 mg per day (take one 150 mg tablet twice a day). If needed, your doctor may increase your dose to a maximum of 600 mg per day (take one 300 mg tablet twice a day).
- MANERIX should always be taken after meals.
- You should swallow the tablets whole with water. Do not chew them.

Are there any dietary restrictions while on MANERIX?

- No special dietary restrictions are necessary while on MANERIX. Examples of amounts of foods that can be safely eaten are: up to 7.5 times the normal serving of aged or overripe cheese, up to 1 kg (2.2 lb) to 2 kg (4.4 lb) of mild cheese, up to 200 g (7 oz) of strong cheese, up to 70 g (2.5 oz) of Marmite yeast extract.

What should you do if you forget a dose of the medication?

- If you forget to take a dose of MANERIX take it as soon as possible, then just carry on with the regular times you take your medication. If you remember your missed dose close to the time for your next dose, do not take the missed dose.
- It may be a good idea to ask your doctor or pharmacist ahead of time what to do about missed doses.

What else should you remember when taking MANERIX?

- MANERIX may take from a few days to several weeks to be really effective, so patience is needed to give the drug a chance to work.
- It is very important that the program is not discontinued, interrupted, or changed in any way without consulting your doctor. If any change in medication or alteration in dose is required, this should be done at the discretion of the doctor.
- Do tell your doctor if you are feeling worse after you have begun treatment.
- Exercise extreme caution when driving an automobile or performing hazardous tasks.

What are the possible unwanted effects of MANERIX?

Unwanted effects are possible with all medicines. Tell your doctor or pharmacist as soon as possible if you do not feel well while you are taking MANERIX.

Some of the most common unwanted effects which may occur are:

- Insomnia
- Dizziness
- Nausea
- Headaches

How can you deal with these unwanted effects?

- Some unwanted effects are less likely to occur if MANERIX is taken after meals.
Some unwanted effects may go away as therapy is continued and your body adjusts to the medicine.

What possible effects require immediate medical attention?

Call your doctor immediately if a combination of the following symptoms occur:

- Severe throbbing headache which starts at the back of the head and radiates forward
- Neck stiffness
- Heart fluttering, fast or slow heart beat

If you are concerned about these or any other unexpected effects while on MANERIX talk with your doctor or pharmacist.

What should you do in case of an overdose or accidental taking of MANERIX?

- Signs and symptoms of overdose with MANERIX include:

Nausea, vomiting, drowsiness, confusion, slurred speech, memory impairment, reduced reflexes, agitation, increased blood pressure and seizures.
- Contact your doctor and/or poison control centre immediately if you suspect you have taken an overdose or someone else accidentally takes your MANERIX. If you are unable to contact them, go to a hospital emergency department for medical help.

How should this product be stored?

- Keep out of the reach of children.
- Store in a clean dry area at room temperature (15-30 °C).
- Keep container tightly closed.

What does MANERIX contain?

- MANERIX is available in 150 mg (pale yellow) and 300 mg (white) single scored, oval, film-coated tablets.
- Each pale yellow tablet contains 150 mg of the active ingredient moclobemide and each white tablet contains 300 mg of moclobemide. Tablets also contain additional (non-medicinal or inactive) ingredients.

These ingredients are:

Cornstarch, ethylcellulose, *iron oxide, lactose, magnesium stearate, methylhydroxypropyl cellulose, polyethylene glycol, povidone, sodium starch glycolate, talc, and titanium dioxide.

*Iron oxide is present only in the 150 mg tablets

REMINDER: This medicine has been prescribed only for you. Do not give it to anybody else. If you have any further questions, please ask your doctor or pharmacist.

AVAILABILITY OF DOSAGE FORMS

MANERIX (moclobemide) is available in 150 mg (pale yellow) and 300 mg (white) single-scored, biconvex film-coated tablets in bottles of 100 tablets.

PHARMACOLOGY

ANIMAL

Pharmacodynamics

In vitro, Ex vivo: Liver and brain tissue homogenates were incubated with moclobemide and tested with the MAO substrates serotonin (5-HT) and phenylethylamine (PEA) in order to characterize moclobemide as an inhibitor of MAO-A or MAO-B, respectively (Table 1).

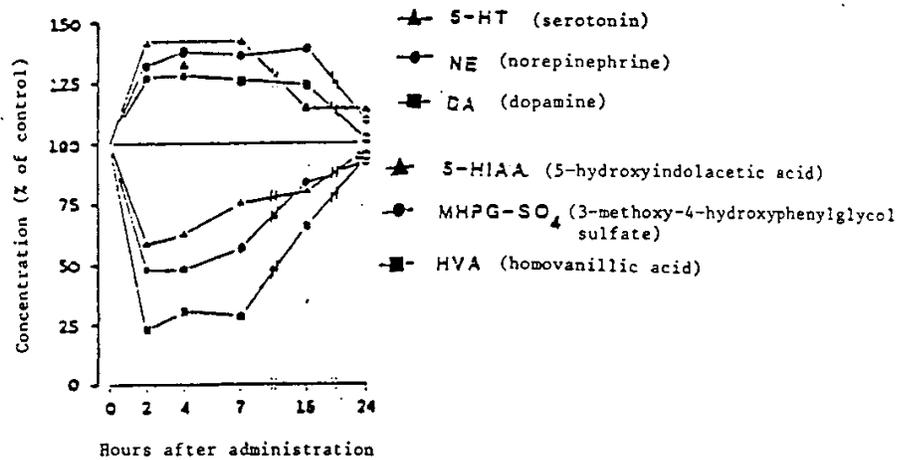

Table 1: *In vitro* and *ex vivo* MAO Inhibition in Liver and Brain Tissue Homogenates

Homogenate	Man		Rat	
	5-HT	PEA	5-HT	PEA
Liver Brain (<i>In vitro</i> , IC ₅₀ , Fmol/L)	12 11	>1,000 >1,000	4 8	220 70
Brain (<i>Ex vivo</i> , ED ₅₀ , Fmol/kg p.o.)			10	98
Liver Brain (<i>Ex vivo</i> , ED ₅₀ , Fmol/kg i.p.)			0.5-0.9 5.0-7.5	9-12 110 - _≥ 200

In *in vitro* rat brain models, moclobemide had no effect on the synaptosomal uptake of serotonin, dopamine and norepinephrine.

In vivo: After the administration of a 50 mg/kg oral dose of moclobemide to rats, slight elevations in cerebral norepinephrine, dopamine and serotonin concentrations, lasting 16 hours, were observed. Values had returned to control levels by 24 hours after administration. Concentrations of the monoamine metabolites were reduced maximally by two and seven hours after administration but had returned to control levels by 24 hours (Figure 1).

Figure 1: Changes in activities of brain monoamines and their metabolites with time after oral administration of 50 mg/kg moclobemide in rat. Points represent percentages of controls (saline) and are means of five single values.

Moclobemide was also active in animal models considered predictive for antidepressant activity:

- (1) It reversed monoamine releaser-induced sedation and ptosis in mice with a duration of action of less than 16 hours ($ED_{50} = 30$ mg/kg i.p.)
- (2) In cats, moclobemide dose-dependently suppressed REM sleep ($ED_{50} = 18.6$ mg/kg i.p.) without disturbing the sleep-wakefulness cycle (10-30 mg/kg i.p.), and
- (3) In the behavioural despair test in mice, moclobemide decreased the immobility score ($ED_{120} = 43$ mg/kg). In addition, moclobemide potentiated the 5-hydroxytryptophan-induced behavioural triad (head twitching, tremour and abduction) in mice ($ED_{50} = 1.0$ mg/kg i.p.).

Drug Interactions

A 100 mg/kg p.o. single dose of moclobemide potentiated the effects of single dose meperidine, morphine and dextropropoxyphene in groups of 10 mice. Following repeated dosing with analgesics, no significant potentiation was observed. In groups of 6 rats, there was no acute interaction between moclobemide and hydroflumethiazide, but sodium excretion was increased following the repeated administration of 100 mg/kg p.o. moclobemide. Moclobemide (100 mg/kg p.o.) potentiated the anti-inflammatory action of ibuprofen in groups of 5 rats. A possible antagonism was found with ouabain (mice) and prazosin (rats). An antagonism with furosemide was observed (rats).

Pharmacokinetics

The pharmacokinetic profile of moclobemide was determined in rats and dogs. Following oral administration, moclobemide was rapidly absorbed, reaching peak concentrations within 10 minutes in rats and 0.5-1 hour in dogs. A hepatic first-pass effect reduced absolute bioavailability to 10-20% and 67% in rats and dogs, respectively. In dogs, maximum plasma concentrations increased proportionately with increasing doses (5-100 mg/kg) and declined with a terminal half-life of approximately 1-2 hours. Distribution and metabolism were extensive in both species; only 1-3% of the dose was recovered in urine as intact drug. The major route of elimination after metabolism was via the kidneys. Approximately 66-90% of the administered dose was recovered in the urine, primarily within the first 24 hours. The main urinary metabolites in rat were the N-oxide metabolite (13%), p-chlorohippuric acid (11%) and the secondary amine (8%). In dogs, p-chlorohippuric acid,

the secondary amine and the N-oxide accounted for 36%, 22% and 7% of the dose, respectively. The protein binding of moclobemide in plasma from dogs ranged from 27% to 44%.

TOXICOLOGY

Acute Toxicity

LD₅₀ (moclobemide)

Species	Strain	Route	LD ₅₀ (mg/kg)	Observation Period
Mice	Fü SPF	orali.p.	1,141572	24h + 10 days
	Charles River CFI	oral i.p. s.c.	730-800 450-530 940->1,000	14 days
Rats	Fü SPF	oral i.p.	4,138-4,444 678	24h + 10 days 10 days
	Charles River CD	oral i.p.	1,300 530	14 days
Rabbits	New Zealand White	oral	800	14 days

Most frequently observed signs and symptoms were decreased motor activity, muscle relaxation, respiratory depression, loss of righting reflex, ataxia, sedation, hypnosis, salivation, tonic-clonic convulsions, tremors, and corneal opacity.

Subacute Toxicity

In an oral pyramiding dose toxicity study, moclobemide was dispersed in starch, encapsulated and administered to four dogs (two/sex) at doses of 0 (starch capsule) 3, 10, 30, 100, 300 and 1,000 mg/kg.

The dogs were essentially asymptomatic following doses of 3, 10, 30 and 100 mg/kg. After the 300 mg/kg dose, three dogs exhibited emesis. There was a slight 34% reduction in food consumption in female dogs and the platelet count of all dogs was slightly elevated (24%). Following the administration of the 1,000 mg/kg dose, all four dogs exhibited emesis, excessive salivation, decreased motor activity and half-shut eyes. Three dogs had tremors and two of four dogs were dazed, ataxic and displayed jerking movements of the head. One dog was disoriented and exhibited lacrimation. Food consumption was markedly reduced (92%) in male dogs but only slightly decreased (42%) in female dogs; food consumption returned to pretreatment levels one day after dosing. The platelet count was slightly elevated one (20%) and seven (22%) days after the final dose.

Long-term Toxicity

Long-term toxicology studies have been conducted in rats and dogs:

Species	Route of Admin.	Maximum Dose (mg/kg)	Treatment Duration
Rats	i.v.	50	4 weeks
	p.o.	300	14 weeks

	p.o.	270	26 weeks
	p.o.	250	18 months
Dogs	i.v.	50	4 weeks
	p.o.	200	12 weeks
	p.o.	100	26 weeks
	p.o.	125	12 months

Rats

1. Four-Week I.V.

Moclobemide (25 mg/mL) was administered intravenously for four weeks to rats (12/sex/group) at doses of 0 (saline control), 10, 20 or 50 mg/kg/day.

The 50 mg/kg/day dose produced tonic-clonic convulsions immediately after injection (males only), followed by slight sedation lasting approximately 30 minutes (males and females) and one male death. A moderate dose-dependent reduction in body weight gain (15% at the highest dose) was seen in male rats.

2. Fourteen-Week Oral

Moclobemide was administered as a dietary admixture for fourteen weeks to rats (6/sex/group) at doses of 0 (controls), 30, 100 or 300 mg/kg/day.

Food consumption and body weight gain were reduced in a dose-dependent manner; at the highest dose, weight gains of 15-60 g were noted compared to increases of 101-229 g in the control group. Immediate moderate to large weight gains occurred at the end of the 14-week treatment period.

The slight increases in GOT, GPT, alkaline phosphatase and blood sugar observed in all treated groups relative to controls were considered not to be drug-related. Administration of 100 or 300 mg/kg/day dose of moclobemide was associated with a slight transient depression of total serum protein in male rats. A small delay in bromsulphalein elimination was observed in week 12 in two female rats receiving the 100 mg/kg/day dose.

3. **Twenty-Six Week Oral**

Moclobemide was administered as a dietary admixture for 26 weeks to rats (20/sex/group) at doses of 0 (controls), 30, 90 or 270 mg/kg/day.

Slight piloerection was periodically observed in high-dose animals from day 30 onward. Bodyweight gains were reduced in a dose-related manner; at the highest dose, male and female bodyweights were 61% and 71% of controls, respectively.

Increases in hemoglobin and mean cell hemoglobin concentration (MCHC) were evident in treated animals of both sexes after 6 weeks of treatment. In most cases these increases, which ranged from 2-16% above control values, were statistically significant. Similar increases (2-11%) were seen in high dose animals of both sexes after 13 and 24 weeks of treatment. All treated females showed increases in GOT after 2 and 6 weeks that were statistically significantly different from controls in most cases. A similar pattern was evident in middle and high dose females after 13 weeks. These increases ranged from 14-41% above control values. After 24 weeks, GOT values in treated females were within normal range.

Macroscopic examination at necropsy revealed a slightly increased incidence of gastrointestinal reddening in treated animals, particularly in males. Small spleens were occasionally noted, predominantly in high-dose females. The majority of absolute organ weights showed statistically significant reductions in treated animals associated with the reduced bodyweight gain. Treatment related increases in relative organ weights were observed in lungs (7-24%), kidneys (4-12%), thyroids (14-43%; males only) and gonads (0-56%).

4. **18-Month Oral**

Moclobemide was administered as a dietary admixture for 18 months to rats (20/sex/group) at doses of 0 (controls), 10, 50 or 250 mg/kg/day.

Body weight development was dose dependently retarded in both sexes. Blood chemistry examinations showed a slight tendency to minimally increased alkaline phosphatase and GPT values in rats treated with 250 mg/kg/day moclobemide.

In male rats receiving 250 mg/kg/day moclobemide, relative heart and liver weights (adjusted to a body weight of 100 g) were reduced by 8.3% and 12.8%, respectively, compared to controls. In females of the same dosage group, adjusted relative ovary and brain weights were decreased 16.8% and 32.1%, respectively, compared to controls.

Dogs

1. **Four-Week I.V.**

Moclobemide (25 mg/mL) was administered intravenously for four weeks to dogs (3/sex/group) at doses of 0 (saline control), 12.5, 25 or 50 mg/kg/day.

During the first days of the experiment, animals treated with 25 mg/kg/day moclobemide became slightly sedated shortly after drug administration. Moderate to marked sedation, lasting one to two hours after injection, was noted in the 50 mg/kg/day dosage group throughout the study. CNS-related head-shaking was also observed at this dose.

2. Twelve-Week Oral

Moclobemide capsules were administered for twelve weeks to dogs (4 males and 2 females/group) at doses of 0 (empty capsule), 20, 60 or 200 mg/kg/day.

Dogs administered 60 mg/kg/day moclobemide had a 5% weight loss during the first weeks of the study. Ten to fifteen percent reductions in RBC counts, hematocrit and hemoglobin occurred in some of the dogs in this group. Biochemically, only plasma cholesterol values were affected, decreasing slightly in some of the dogs.

At the 200 mg/kg/day dosage, dogs showed immediate, severe weight losses amounting to approximately 10% per week for the first two weeks. After six weeks of moclobemide administration, body weights of five of the six animals in this group were decreased to 60 to 70% of their starting weights. Moclobemide administration was stopped, and three dogs were sacrificed due to cachexia. In the three remaining dogs, immediate and rapid weight gains were observed following treatment discontinuation. In one week, the body weights of these animals were increased to 25% above their weights at six weeks.

Reductions of approximately 25% in RBC counts, hematocrit and hemoglobin concentrations were observed after six weeks of the 200 mg/kg/day moclobemide dose. Slight increases in GOT and GPT, a reduction in plasma cholesterol concentrations; a slowing of the heart rate and lengthening of the QT interval; very low heart weights in two dogs, and slight atrophy of the myocardial fibers were also observed at this dose. After three weeks without moclobemide, these changes showed marked improvement.

3. Twenty-Six Week Oral

Moclobemide capsules were administered for twenty-six weeks to dogs (4/sex/group) at doses of 0 (empty capsule), 10, 30 or 100 mg/kg/day.

Dogs administered 100 mg/kg/day moclobemide began to lose weight from week six, and body weights remained virtually constant until study termination. However, moclobemide had no effect on the consumption of food and water.

Moderate dose-related decreases in hemoglobin concentration, RBC count, and PCV were noted at week six. These decreases were statistically significant in dogs administered 100 mg/kg/day moclobemide. This effect was less marked during the remainder of the study, but decreases were also statistically significant in females in the high-dose group at weeks 13, 18 and 24. A dose-related reduction in plasma cholesterol concentrations was observed in female dogs; decreases in this parameter were statistically significant at the high dose throughout the study, at 30 mg/kg/day after weeks 13 and 18, and at the low dose after 13 weeks.

At the high-dose, absolute uterus weights decreased, and absolute liver weights increased in males. Relative liver weights were increased at 30 and 100 mg/kg/day; relative thyroid and adrenal weights were increased at the high dose, and relative lung weights were increased at all three moclobemide doses. Decreased relative uterus weights were seen in the high-dose group.

Microscopic examination of tissue sections revealed the following:

- a) Anestrus, characterized by an absence of normal reproductive-cycle changes in the uteri, ovaries and mammary glands of all female dogs administered 100 mg/kg/day moclobemide.
- b) Minimal hepatic fibrosis, indicative of low-grade liver injury, occurring in three males and three females in the high-dose group, and in one of four females given 30 mg/kg/day moclobemide.
- c) A minimal increase in the incidence and severity of thymic regression in male dogs in the high-dose group.

4. Twelve-Month Oral

Moclobemide capsules were administered for 12 months to dogs (5/sex/group) at doses of 0 (empty capsule), 5, 20 or 100/125 mg/kg/day. As a result of good tolerance, the dose in group four was increased from 100 mg/kg/day to 125 mg/kg/day after six months. One dog of each sex from each dosage group continued to be examined for an additional six weeks after drug administration ended (recovery period).

At the highest dose, a moderate 10-20% reduction in RBC counts, hemoglobin and PCV was observed in females after 9 and 12 months of moclobemide administration. These values remained within the lower limit of the physiological range during the study and returned to normal during the recovery period. Mean triglyceride values were minimally increased in males and decreased in females. Cholesterol levels were minimally to moderately decreased (20-40%) in both sexes at most examinations. Alkaline phosphatase showed a tendency to higher values in males. Triglyceride, cholesterol and alkaline phosphatase values returned to normal during the recovery period.

At the highest dose, liver and adrenal weights were increased. Histological examination of the liver revealed a slight increase in hemosiderin deposits relative to other groups, especially in females. Minimal fibrosis was observed in five dogs and an additional case occurred in one animal administered 5 mg/kg/day.

Mutagenicity

Ames Test: In the Ames test, with and without metabolic activation, moclobemide concentrations of 0.02-20 mg/plate were not mutagenic for Salmonella typhimurium strains TA 1535, TA 1537, TA 1538, TA 98 and TA 100.

Micronucleus Test (Mouse Bone Marrow): Moclobemide did not induce chromosomal breakage or mitotic non-disjunctions in mouse bone marrow after a single dose of 800 mg/kg by gavage.

Hamster V-79/HGPRT Assay: Moclobemide concentrations of 1.0 - 4.0 mg/mL (without metabolic activation) or 2.0 - 3.4 mg/mL (with metabolic activation) did not induce forward mutations at the HGPRT locus in Chinese Hamster V79 cells.

Induction of Chromosomal Abberations (Human Lymphocytes): Moclobemide concentrations of 200-600 mg/mL (without metabolic activation) or 600-4,000 mg/mL (with metabolic activation) did not induce chromosomal damage in human peripheral lymphocytes.

Unscheduled DNA Synthesis (Rat Hepatocytes): Moclobemide did not induce DNA damage resulting in unscheduled DNA synthesis, in freshly isolated rat hepatocytes at 0.1 - 2.0 mg/mL, or in cultured human fibroblasts at 0.4 - 1.2 mg/mL.

Carcinogenicity

1. Eighty Week Oral - Mice

An 80 week oral (dietary admixture) carcinogenicity study with moclobemide was conducted in mice (50/sex/group) at doses of 0 (control-1), 0 (control-2), 10, 50 or 250 mg/kg/day.

Body weight development was similar for both male and female mice at moclobemide doses of 10 and 50 mg/kg/day. At 250 mg/kg/day, body weights were reduced by 10% relative to the other groups. Relative kidney weights in the highest dose group were increased approximately 15% compared to control animals.

Neoplastic lesions were observed in the lungs, hemolymphoreticular system, liver, ovaries and pituitary gland in both the control and treatment groups. The incidences of lesions which occurred more frequently in treated animals than in controls are summarized below:

	Lungs Bronchioalveolar Tumours		Hemolymphoreticular System Malignant Lymphomas	Liver Adenomas
	(Females)	(Males)	(Males)	(Males)
Control-1	33%	52%	4%	4%
10	36%	46%	10%	14%
50	40%	52%	8%	14%
250	57%	38%	4%	16%
Control-2	42%	36%	2%	12%

The dose-related increase in pulmonary tumours observed in females did not reach statistical significance. The neoplastic lesions noted in this study were considered to reflect the spectrum of spontaneous neoplasms usually observed in mice of this strain and age.

2. Two Year Oral - Rats

A two-year oral (dietary admixture) carcinogenicity study was conducted in rats (50/sex/group) at moclobemide doses of 0 (control -1), 0 (control-2), 9, 45 or 225 mg/kg/day.

Thirty-seven males and 60 females died prematurely. In both sexes, survival was greater at 45 and 225 mg/kg/day moclobemide than at 0 and 9 mg/kg/day. The negative dose-related trend was significant for males and for both sexes combined.

A total of 136 rats, 71 males and 65 females, had foci or hyperplasia. The clearest effect of treatment was for hepatocellular hyperplasia. Of the 23 cases reported, one occurred in the combined control groups, none was seen at 9 mg/kg, 7 occurred at 45 mg/kg and 15 at 225 mg/kg. The dose-related trend was similar and highly significant in each sex individually. The increases reached statistical significance at a moclobemide dose of 225 mg/kg for males and females individually and at 45 mg/kg for both sexes combined.

An increased incidence of alveolar foam cell aggregates was noted in the lungs of male rats at the 45 and 225 mg/kg/day doses and in females at the 9, 45 and 225 mg/kg/day doses. In

addition, an increased incidence of small clusters of greenish-brown pigmented alveolar macrophages was diagnosed in the males receiving 225 mg/kg/day. Microscopic examination revealed no qualitative morphological differences between the alveolar macrophages of treated and control rats. The number and size of type II pneumocytes, however, were increased in treated rats compared to controls.

Reproduction and Teratology

1. Fertility and General Reproductive Performance

A fertility and reproductive performance study was conducted in rats at oral (gavage) doses of 15, 40 or 100 mg/kg/day. Thirty-six males were treated 70 days prior to and during mating and 36 females for 14 days prior to mating until the 22nd day of lactation.

Nervousness and salivation were observed in both sexes. No treatment-related parental mortality occurred. The median weight gain of parental males in the 100 mg/kg dose group was significantly reduced throughout the first three weeks of treatment. A slight decrease in median body weight at weaning was observed in dams in the 40 mg/kg dose group. The body weights of females in the 100 mg/kg dose group were decreased throughout most of the treatment period.

Mating success, gestation length, and pregnancy outcome were not influenced by treatment in any group. A slight decrease in the median number of corpora lutea per pregnant female in the two upper dose groups was considered not to be drug-related.

Embryonic and fetal resorption rates were comparable to controls in all dose groups. In the highest dose group, the number of pups born alive was slightly decreased. Median body weights of the F-1 pups were comparable to controls in all dose groups during the lactation period.

The survivability of the F-1 pups was slightly to moderately reduced in the 40 and 100 mg/kg dose group, respectively. The examination of pups which died during the lactation period and of pups in the necropsy sub-groups revealed no abnormality considered to be drug-related.

When the rats from the F-2 generation were mated, the number of implantations, resorptions, and pups born were comparable to controls in all dose groups. At lactation days 1 and 4, a delay in pup weight development and a reduction in survivability were observed in the 100 mg/kg group.

The tests for physical and functional development as well as those for learning and memory revealed no statistically significant findings.

2. Embryotoxicity and Teratology - Rats (Oral)

A teratology study was performed in 40 mated female rats at oral (gavage) doses of 25, 70 or 200 mg/kg/day from day 7 to day 16 of gestation inclusively. Another group of 40 rats received only the vehicle and served as control animals. On the 21st day of gestation, the rats in each dosage group were allocated to either a necropsy or a rearing subgroup.

During the treatment period, maternal weight gain was slightly retarded in the 25 and 70 mg/kg/day groups and moderately reduced in the 200 mg/kg group; by day 17 of gestation, dam weight gains in the low and mid-dose groups were approximately 72-85% of control

values. In the high-dose group, dam weight gains were approximately 44% of control values. The reproductive process was not impaired in any of the dosage groups.

In the rearing experiment, there was no indication of a postnatal effect caused by drug administration at 25 or 70 mg/kg/day. At the 200 mg/kg/day dose, the survivability of the pups during the lactation period was reduced slightly to 85%.

The examination of skeletal abnormalities revealed no findings deviating from the norm except an increased number of incised vertebral bodies and poorly ossified sternebrae in the higher dosage groups. These findings indicate a slight retardation of ossification. An examination of soft tissue revealed no malformations in the groups given drug at 25 and 200 mg/kg/day. In the mid-dose group, two fetuses had an enlarged renal pelvis, one fetus had an enlargement of the right lateral cerebral ventricle, and one fetus had exencephaly and spina bifida. Due to their infrequent occurrence, these malformations are considered to be of a spontaneous nature.

3. Embryotoxicity and Teratology - Rabbits (Oral)

A teratology study was performed in 20 mated female rabbits at oral (gavage) doses of 15, 40 or 100 mg/kg/day from day 7 to day 19 of gestation, inclusively. Another group of 20 rabbits received vehicle only and served as controls. The dams were sacrificed on day 30 of gestation and examined for drug effects on fertility and fetal gross abnormalities.

A dose-related retardation of maternal weight gain was observed during the treatment period; by day 20 of gestation, dam weight gains were 85%, 68% and 51% of control values in the low, mid and high dose groups, respectively.

The reproductive process (mean number of corpora lutea and implantations) was not impaired in any of the dosage groups. In the 15 mg/kg/day group, the resorption rate was significantly higher than in controls (33.6% of implantations versus 12.6% of implantations). As the number of resorptions in the higher dosage groups was significantly lower than in the 15 mg/kg group, and within the control range, this finding may not be drug-related. In the 100 mg/kg group, three dams aborted a total of 19 fetuses, two of the dams had severe diarrhea before aborting. One dam in each of the 15 mg/kg and the 40 mg/kg groups aborted.

Detailed examinations of the fetuses for skeletal abnormalities revealed that one fetus in the 40 mg/kg group had a missing medulla oblongata; omphalocele occurred in one fetus in the 15 mg/kg group and in one fetus in the 40 mg/kg group; and in the 40 mg/kg group, four fetuses in one litter had a thick, flatulent abdomen; one fetus had a protruding tongue. Due to their infrequent occurrence at low dosages only, these malformations are considered to be of a spontaneous nature.

4. Perinatal and Postnatal - Rats (oral)

A perinatal and postnatal study was performed in 24 mated female rats/group at oral (gavage) doses of 30, 70 or 150 mg/kg/day from day 16 of gestation up to the end of the lactation period (day 23). Another group of 24 rats received the vehicle only and served as control.

Alopecia and mild transient diarrhea were observed in single animals of all treatment groups including controls, and were therefore regarded as not treatment related. Weight development was slightly delayed in dams in the 150 mg/kg dose group throughout the entire treatment period. No drug- related maternal death was observed. Reproductive parameters were not affected by treatment, with the exception of a slight nonsignificant increase in the resorption rate of dams in the 150 mg/kg dose group.

The median weight development of the F-1 pups during the lactation period was slightly delayed in all dose groups. A slight decrease in pup survivability was observed in the highest dose group. No treatment related gross external or visceral abnormalities were observed in living or dead pups. Tests of the physical and functional development of the F-1 generation revealed no statistically significant findings in any dose group.
